

a wake up call for sustainable buildings

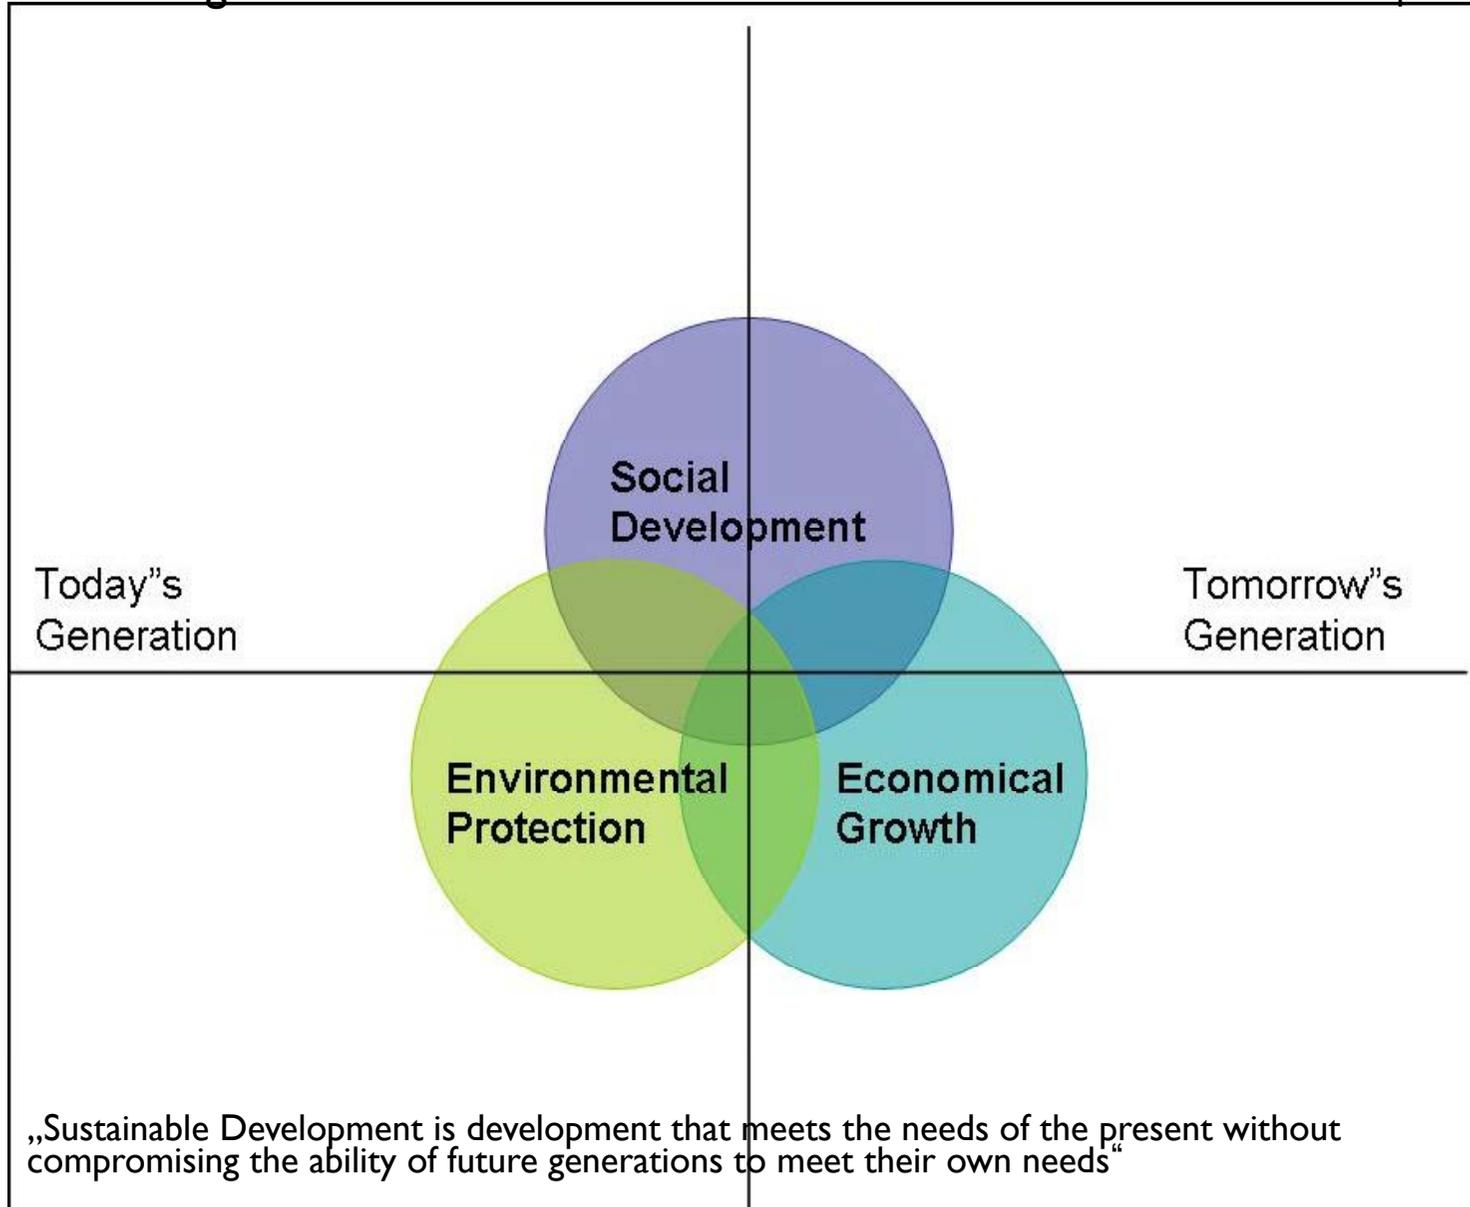

Peter Schürch, architect SIA SWB

Prof. university of applied sciences AHB, Bern

Halle 58 Architekten, Bern _ 7.2.2019

lifecycle_architecture

A building has a long life cycle, so its effect on the environment is a long and continuing issue to consider. World Business Council for Sustainable Development

„Sustainable Development is development that meets the needs of the present without compromising the ability of future generations to meet their own needs“

LE CITTÀ COME MODELLI DI SOSTENIBILITÀ CITIES AS MODELS OF SUSTAINABILITY

La forma delle città influenza sull'ambiente e sul cambiamento climatico globale. Le città più dense e compatte usano meno energia e producono meno inquinamento, mentre le città sparse come Los Angeles e Città del Messico richiedono necessariamente un maggiore consumo di combustibili e generano più agenti inquinanti. Con il contributo di un'efficace sistema di trasporto pubblico, le metropoli ad alta densità costituiscono un modello positivo di crescita sostenibile: questo è ad esempio il caso di Barcellona. Londra e Milano, città che stanno accoppiando un numero crescente di persone attraverso l'ibridizzazione delle politiche edilizie del loro centro e il ruolo degli edifici industriali e degli ex complessi industriali, vorrebbero imitare l'adattamento di nuove aree urbane situate oltre le loro frontiere.

The shape of a city affects the environment and global climate change. More compact and dense cities use less energy and create less pollution, while dispersed cities like Los Angeles and Mexico City require more fuel and create more pollution. High-density cities, supported by effective public transport systems, offer positive models for sustainable growth as do Barcelona, London and Milan, cities that are encouraging denser numbers of people by introducing development in the centre, reusing redundant buildings and re-industrial land rather than building on green field sites beyond their boundaries.

_a possible path towards better architecture

_sustainable & high quality design

_future-capable architecture

五条可持续性发展的原理

FIVE PRINCIPLES OF HOW TO BUILD A SUSTAINABLE CITY

When the grey haze in front of the sun lifts, we can anticipate the bright future we would like to live in. We imagine cities built on radically green designs, sustainable energy, and non-toxic recyclable materials. Market forces and political power will help to propel us into the green future - there is no other responsible alternative! Our design for a Green Central Business District is guided by five very simple principles, which together can make a sustainable city.

1. THE FUTURE BELONGS TO THE CITIES!

Sprawl eats land and puts stress on the ecosystem by increasing the need for transportation - be it individual or public. Planners can make better use of space, energy and public investments by placing buildings, different functions and nature close to each other. This will promote walking, cycling, public transit and foster community

2. ENERGY EFFICIENCY CREATES VALUE

Waste is costly in all imaginable dimensions. Consuming less water, power and materials is cheaper! Well-insulated, naturally ventilated buildings full

of natural light will help their users waste less energy. Power-saving appliances will pay for themselves in the long run.

3. RENEWABLE ENERGY IS ABUNDANT ENERGY

The use of conventional energies comes at high costs; and the resources are not end-less. Renewable alternatives promise clean energy: wind turbines, solar arrays, wave power units, small-scale hydro-electric generators, or geothermal systems. There is no responsible alternative to not integrating these solutions wherever possible!

4. QUALITY IS WEALTH

More is not better - but better is better! People do not need bigger apartments - they need different floor plans. People do not need bigger cars - they need better cycle paths or public transport! People do not need more stuff to throw away - they need quality that will last!

5. CLOSED LOOP CITY

Every neighbourhood, urban district and city needs to be conceived as a "cycling economy" where production, consumption, waste and circulation are understood as an integrated ecological chain

guidelines for sustainable architecture

1 foresight

foresight of future trends and development
flexibility and creativity, integral thinking

2 innovation

interdisciplinary teamwork, inventing integral solutions
adapting and transforming old knowledge

3 economical efficiency

economically reasonable for investors and residents over the whole lifecycle

4 ecological responsibility

efficiency in energy and resources, biodiversity, urban mining, safe and create green spaces

5 social responsibility

involvement of residents and neighbourhood
creation of social meeting spaces

6 cultural diversity and aesthetic quality

high quality in design, competitions
regional identity, think global - built local

7 project-specific topics

guidelines for sustainable architecture

I foresight

foresight of future trends and development
flexibility and creativity, integral thinking

_searching for sustainability

_thinking about future generations – act now

_sufficiency (quality from moderation)

_cradle to cradle, upcycling, reuse, recycling

_why in the future less has to be more

_environmentally friendly facilities and materials

_health-conscious residences with high quality design

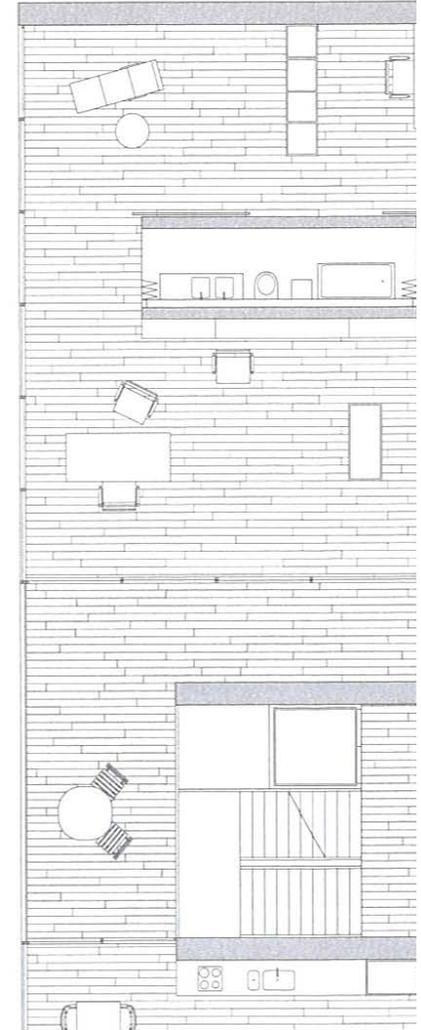

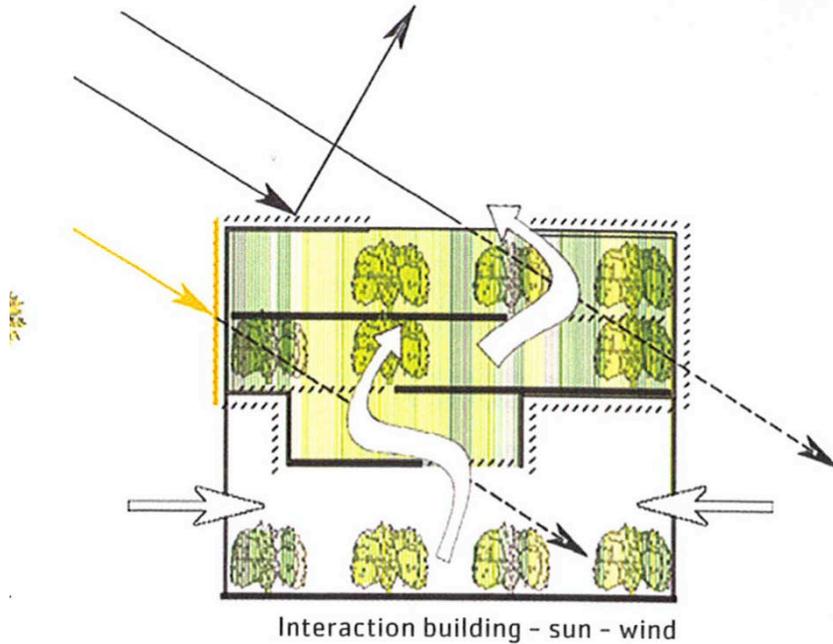

What does a human being need to live happily?

fact: a human being consumes 87 500 Liter air per week

innovation

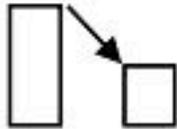

interdisciplinary teamwork, inventing integral solutions
adapting and transforming old knowledge

- product research
- holistic thinking
- learning
- education
- brain food
- nature-made

ecological responsibility

energy efficiency

Einsparen von Nutzenergie
energy saving

$\eta \rightarrow 1$

Effizienz bei der Nutzung nicht erneuerbarer Energie
non renewable energy efficiency

Einsatz regenerativer Energie
use of renewable energy

Energiefragen sind nicht einfach den Gebäudetechnikplanenden zu überlassen. Energiekonzepte am Gebäude sind grundsätzliche Gestaltungsfragen. Gleichwertig wie Städtebau, Raumfolgen, Fassaden, Konstruktion, Typologien, Kosten, ua.

GEBÄUDETECHNIK
Haustechnikzentralen

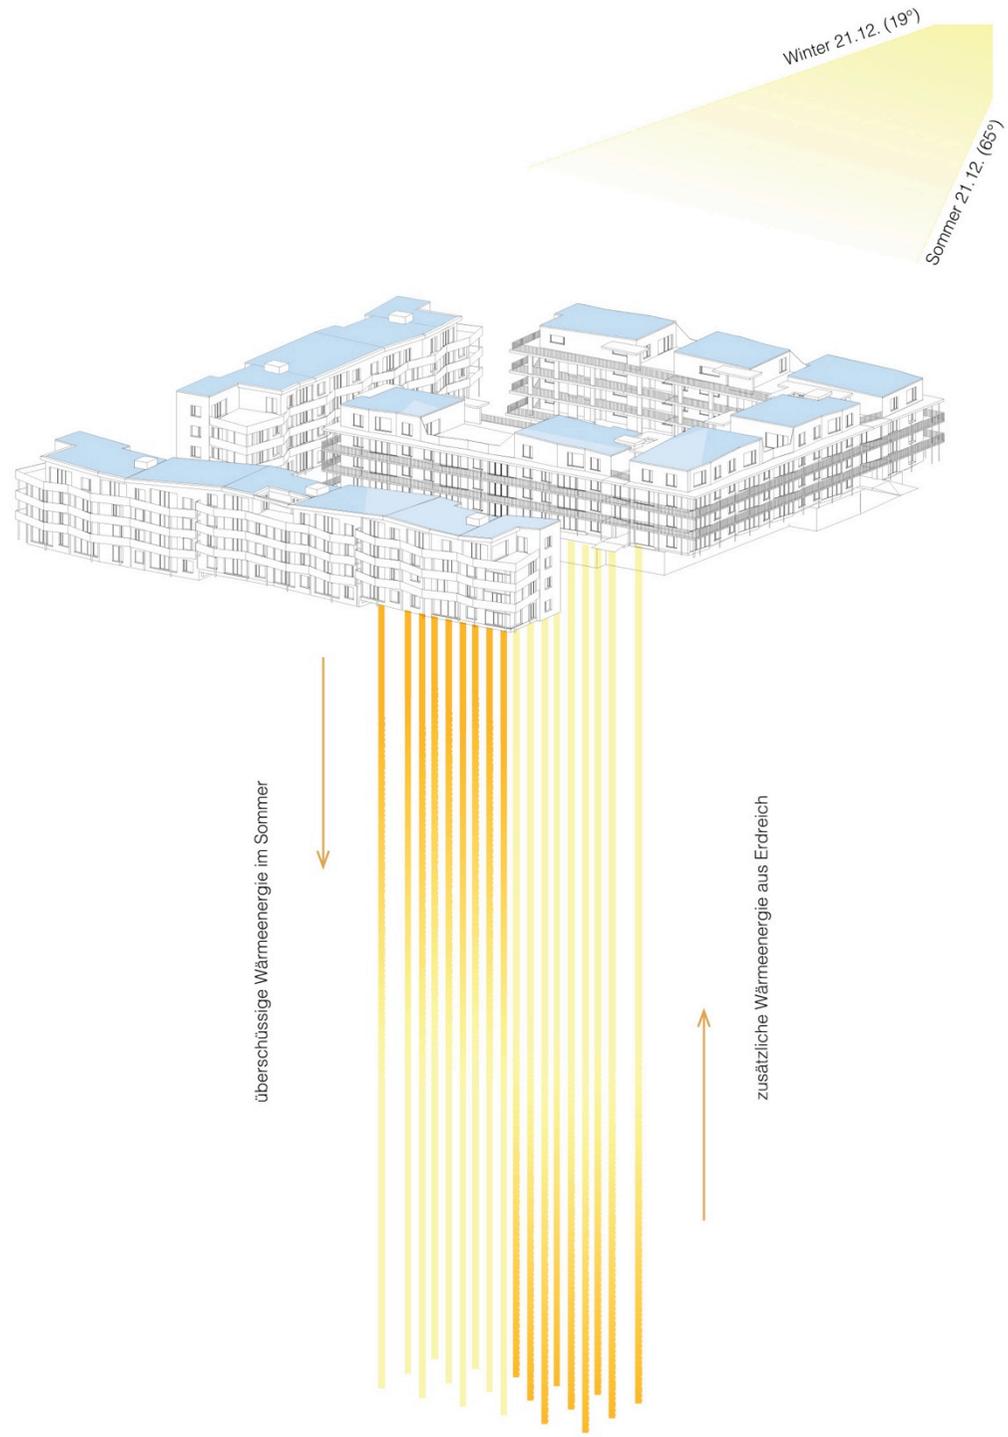

Aufteilung:
5 unabhängige Haustechnikzentralen

geothermal heat pump,

storage earthfield with
5km drills and hybrid
collectors (electricity
and hot water)

Mechanischer Luftwechsel
 Kontinuierliche Lüftung mit Wärme- und Feuchtaustauscher (Erthalpaustauscher) minimieren den Energieverlust, ein Strosslühnen der Wohnungen ist weiterhin jederzeit möglich.

Niedrigtemperaturheizung
 Energieoptimiertes Bodensystem mit teils schwachläufigen Vorlauf-temperaturen (max. 26°).

Wärmeschutzverglasung
 Fenster und Verglasungen mit niedrigem U-Wert, IV-Glas 0,5 W/m²K, verhindern Transmissionsverluste.
Verglasung
 Verglasungen mit relativ hohen g-Werten, ermöglichen zusätzliche Solarenergiegewinne.

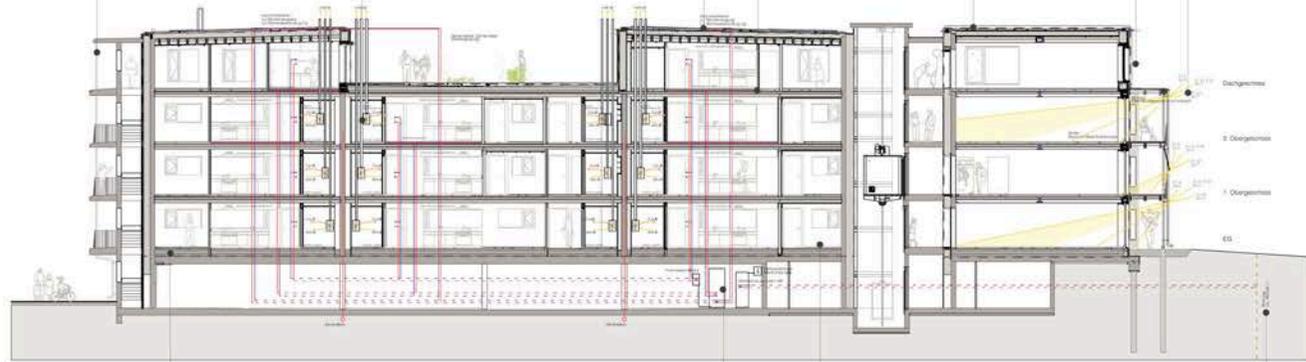

Verschattung
 Umlaufende Balkone verhindern die sommerliche Überhitzung. (im Schema: saisonale Sonnenstände)

Wasserkreislauf
 Versickerung des Dachwassers auf dem Grundstück.

Hybridkollektoren
 Integration der Kollektoren in Dachflächen, Erzeugen von Elektrizität und Warmwasser für das Erdspeichersystem.

Retention durch Dachbegrünung
 Veröhrung der Wasserabgabe ins Erdreich bei Regenfällen.

passive Solarenergiegewinnung
 Ausrichtung grosszügiger Glasflächen nach Süden.

Hochwärmegedämmte, kompakte Gebäudefläche aus Holz
 Bauteile mit niedrigen U-Werten verhindern Transmissionsverluste, führen zu einer hohen Behaglichkeit und zu einem tiefen Energieverbrauch.
 Aussenwand max. 0.1 W/m²K
 Dach max. 0.1 W/m²K
 Decke zu LG max. 0.1 W/m²K

Ökologische Materialisierung
 Die Hybride Holzkonstruktion (Holz/Beton) ermöglicht eine kostengünstige, rationale und ökologische Bauweise. Natürliche Baustoffe führen zu einem guten Raumklima.

Legionellenbekämpfung
 Energieeffiziente Verdrängung der Legionellenbildung durch Frischwassersystem. (RWI)

Erdspeicherspeicherfeld
 Nutzung der Sonnenenergie (Transfer Sommer zu Winter). Das Erdspeichersystem wird jeweils im Sommer mit dem Warmwasser der Hybridkollektoren aufgeladen (Sandseriete auf ca. 25°) und im Winter wird diese Wärme der Wärmepumpe zugeführt.
